LAB

- Using the techniques that you learned in this section, create a Docker container that deploys Nginx webserver. Hint: search hub.docker.com for nginx image and take note of the different options and environment variables that can be used with the container.
- Configure Docker to forward traffic arriving at port 8081 on the host to port 80 on the container.
- Using name volumes, assign a new volume to the container where the web files can be added to the container. Add some HTML files and ensure that Nginx is serving those files.
